

What are your thoughts on tokenscale.dev?

TokenScale looks like a well-designed, browser-only explainer for AI pricing and token economics, especially if you want to understand how context growth, batch pricing, and caching change real costs. Its main strength is making abstract token math concrete with familiar content types and live sliders, and it emphasizes that “every reply re-reads the entire conversation,” which is the core cost trap it teaches around.^[1]

What it does well

It appears focused on education first: converting words to tokens, showing per-call and scaled monthly/yearly costs, and comparing standard, batch, and cached pricing modes. That makes it useful for developers, PMs, and anyone trying to reason about prompt budgets without digging through pricing docs. The “no sign-up” and “runs entirely in your browser” messaging is also a good trust signal for a lightweight tool.^[1]

Where it seems useful

If you work with long-context workflows, agent loops, or high-volume API usage, TokenScale seems especially relevant because it highlights the point where large contexts become expensive and may need chunking. It also seems good for quick gut-checks: “How much does this email/chat/novel cost?” rather than precise billing analysis. That makes it more of a teaching and planning tool than a full cost calculator.^[1]

My take

My overall impression is positive: it looks polished, practical, and aimed at improving token awareness rather than selling hype. The biggest potential downside is that tools like this are only as accurate as the pricing assumptions they encode, so I’d treat it as a useful estimator, not a source of record. For someone who cares about AI workflow efficiency, it’s the kind of tool worth bookmarking.^[1]

Would you like a quick comparison between TokenScale and a few other token-cost calculators or tracking tools?
